I. INTRODUCTION

This paper is an attempt to assemble some of the most commonly requested results of the inter-provincial input-output model. We have included a variety of measures - some by industry and province of production, others by commodity and province of purchase. In addition to the usual "multipliers" we have included six simulations of broad aggregates of final demand showing the effects on various incomes by province. One of these is a standardized vector of exports of each province to the rest of the country.

This paper, above all, attempts to provide a broad context within which comparisons can be made. All too often input-output multipliers are used without reference to the framework in which they were calculated. A static input-output model used in a partial context (rather than a total economy simulation) should not be used in an absolute mode but rather for comparative analysis. This restriction is imposed by the very nature of the model which is not sensitive to limits of production capacity nor to variations from the average patterns embodied in the model parameters. Furthermore, an input-output model provides an incomplete measure of impact to the extent that it does not capture the ultimate effects of incomes drained off for taxes, profits and imports. These effects are too complex to be modeled by a simple linear proportional system and the functional relationship between incomes and expenditures becomes less clear.

I. INTRODUCTION

This paper is an attempt to assemble some of the most commonly requested results of the inter-provincial input-output model. We have included a variety of measures - some by industry and province of production, others by commodity and province of purchase. In addition to the usual "multipliers" we have included six simulations of broad aggregates of final demand showing the effects on various incomes by province. One of these is a standardized vector of exports of each province to the rest of the country.

This paper, above all, attempts to provide a broad context within which comparisons can be made. All too often input-output multipliers are used without reference to the framework in which they were calculated. A static input-output model used in a partial context (rather than a total economy simulation) should not be used in an absolute mode but rather for comparative analysis. This restriction is imposed by the very nature of the model which is not sensitive to limits of production capacity nor to variations from the average patterns embodied in the model parameters. Furthermore, an input-output model provides an incomplete measure of impact to the extent that it does not capture the ultimate effects of incomes drained off for taxes, profits and imports. These effects are too complex to be modeled by a simple linear proportional system and the functional relationship between incomes and expenditures becomes less clear.

As an illustration, the size of the income multiplier due to closing the standard I-O model to households is very sensitive to the marginal propensity to consume which is determined mainly by savings and taxes. Now over the last decade we have witnessed a gradual increase of the average personal tax rate and consequently a diminishing income multiplier as measured by the "closed" model. However, transfer payments in the form of unemployment insurance, health plans, pensions etc. have maintained private spending power but the payments are not a direct function of government revenues by taxes on incomes from the production system.(witness the increasing debt). Therefore the "closed" model multipliers become less meaningful or less able to "capture" the complete income effects. Granted, there is some justification for assuming a long term equilibrium such that the transfers to persons ultimately have to be related to the level of income although these could be funded from taxes on corporate earnings or other sources of government revenue. Nevertheless, such considerations can only be examined in a much more articulated framework and are beyond the scope of a simple linear, static model of the production system.

If an absolute multiplier is not realistically obtainable then what sorts of analyses can be done with this type of model? Clearly the least dangerous assertions can be of a comparative form. This is not to say that comparisons are immune to bias from the above mentioned weakness but at least there exists a consistent common basis. This paper provides a variety of tables highlighting the different aspects of the inter-provincial system and thereby allows numerous opportunities for comparing a given multiplier to other benchmark measures such as the six standard simulation displayed in table III. Special attention should be paid to provincial distributions of effects which are the unique feature of this type of model. These can be viewed from a commodity dimension in tables I.C. and from a final demand dimension in tables III.A & III.B. For those interested in income and employment multipliers we have included a sample of in-province (as opposed to total Canada) multipliers by 2 digit S.I.C. in table II.C.

As a final word of warning, these measures are subject to error not only due to the weakness of the simple structure of the model but also due to implications of arbitrary accounting conventions and, not least, by the quality of data which in many areas is no better than a guess. This is the condition of inter-regional input-output and Canada is certainly much more fortunate than most countries in this field.

II. The Data Base

The 1974 interprovincial model is based upon a vast amount of directly observed provincial data. There is relatively complete information on the inputs and outputs of most of the goods producing industries and the levels of activity for most services are available. These are applied to the national patterns to provide estimates at the provincial level for services. Final expenditures by province and generally available albeit at an aggregate level and there are of course conceptual difficulties as to province of expenditure for certain sectors such as moveable capital goods and defence equipment. (In the same way, the designation of "province of production" for such services as transportation, communication, and finance is rather arbitrary).

The methodology for estimating inter-provincial trade was to assemble all available trade data (mainly manufacturing destination of shipments and transportation data for raw materials) and then to reconcile this with supply and use constraints derived from the provincial input-output tables. Since the trade data had certain weaknesses and foreign imports came only by province of entry rather than destination it was important to have very firm constraints on the supply and use. In fact, this need is even more serious at the provincial level then nationally since relatively strong foreign trade data exist for the country as a whole. Adjusting each industry to the corresponding national control total assured consistency but not

necessarily accuracy since the differences were generally prorated. Ideally the balancing of industry totals to Canada constraints should benefit from the commodity reconciliations but this cannot be envisaged until the entire statistical system is more integrated.

Inter-provincial trade of service commodities is the most serious weakness of the data base. Here we have resorted to a somewhat arbitrary designation between "local" and "national" services. the former such as construction, retail trade, and personal services are deemed to be wholly supplied by the province in which they are demanded. The latter such as transportation communications and finance are assumed to follow a general trade pattern which is provided by the aggregate pattern of manufactured goods ignoring imports. This resulting trade matrix reflects the predominance of Ontario as a national supplier followed to a lesser extent by Quebec and at the same time allows for more local intraregional movements.

Ancillary information is required for employment estimation and also for closing the household account. The former data are not generally available by province at the level of detail imposed by the input-output classification and had to be estimated using national allocators.

Closing the model to households requires data on savings and personal taxes by province. This is available from the

provincial accounts publication (Table 10, 13-213). Some difficulties arise in using this information however since the provincial savings rates, even more than nationally, suffer from gaps in the information system. Savings is a residual and is thereby sensitive to errors in other items. Saskatchewan's rate of personal savings was over 20% in 1974 which is reflected in the relatively low income effects in this province (see TABLE III A.8.). However, there are reasons to believe that Saskatchewan's savings rate is generally higher than other provinces'.

III. Description of Tables

The tables are organized in three sections. Table I is from the perspective of a purchase of a dollar of each commodity by province; Table II the production of a dollar's output in each industry, and tables III a standardized final demand by major sector. All simulations include the income effect due to closing the model to households.

All results are expressed in terms of:

a) LABOUR INCOME - the sum of wages & salaries, supplementary labour income and unincorporated business profits;

b) G.D.P. - labour income plus corporate operating surplus;

c) EMPLOYMENT - in person years per $10,000 of production based upon 1974 proportions;

d) GROSS PRODUCTION - Shipments adjusted for inventory change.

1. Table I — COMMODITY SPACE

These tables examine the effects of expenditures on goods. Table I.A. presents the supply position of each province showing the proportions of each commodity satisfying total provincial requirements from each of own-province, the rest of Canada and the rest of the world. Clearly, the local impact of an expenditure depends largely upon the self-supply ratios of the province.

Table I.B is the direct plus indirect effect of a dollar's purchase of each good. The results measure the in-province effects in terms of labour income, G.D.P., employment, and gross production. It is important to note that in these tables the key element is purchases such that if a province produces entirely for export (eg. Newfoundland iron ore) then there is no local purchase and the effect will be nil. In such cases one should refer to table II.B in the appropriate industry. Furthermore, the "Canada" column is an average of all provinces weighted by total purchases of each commodity in the province. To this extent it does not represent the total Canadian effects since it excludes the out-of-province activity. These tables (I.B) are not multipliers per dollar of direct income but rather per dollar of purchase which explains why labour income and GDP are in most

cases less than unity. As a reference point remember that a dollar of expenditure should result in a dollar of GDP (at market prices) less direct and indirect imports. However, when the model is closed to households the expenditures are implicity increased due to the endogenized consumers sector and therefore the total GDP could exceed unity per dollar of endogenous expenditure despite import leakages.

The employment table (I.B.3) has been scaled to reflect person years per $10,000 purchased for ease of presentation. One must be aware that in some cases the measures reflect a very small and unstable statistical sample. Employment can be particularly inaccurate at this level of detail in the smaller provinces due to the incidence of part time and other than paid workers which tend to predominate in small scale establishments.

The relationship between employment and production used for these results is based upon 1974. Current data would reduce the general average by approximately 33 % due to higher average wages.

Table I.C shows for each province, the distribution of GDP over all provinces. This table is quite representative of the factors chosen in this paper consequently, for economy of space it was decided not to include similar tables for labour income, employment, and production.

The GDP tables may be used to approximate the inter-regional model. Most project analysis consists of coding project expenditures to the appropriate commodity group and province of purchase. The model then calculates the direct and indirect effects by province and industry. Once the coding has been done to the 96 commodity level it is straight forward to apply the major items to the appropriate rows in table I.C. Since the relationships are linear the total effects thus obtained may be added to yield a total impact by province in terms of GDP. (This can be translated into employment by using the ratios between tables I.B.3. and I.B.2. Granted this procedure can become quite time consuming when many commodities are involved but for most project analyses the number of important commodities is very small.

2. Table II INDUSTRY SPACE

Table II presents total impact measures and multipliers by province of production at the medium industry level corresponding roughly to the 2 digit level of the S.I.C. In order to give some idea of the size of each sector by province without revealing any confidential information table II.A gives the relative magnitude of production of each industry. It is important to retain some notion of scale in using these measures since they are valid only within a certain range of their 1974 real levels. Indeed, in cells where the production levels are particularly small the measures of total incomes may be enormous due to negative operating surpluses or other anomalies. In some cases an industry may be represented in a province only by the existance of a sales office. (This, strictly speaking, is a case of mis-coding since it should be classified as a wholesaling activity.)

Table II.B is analogous to section I.B. except for the perspective of industry and province of production rather than commodity of province of purchase and the comments pertaining to the latter are relevant.

Table II.C consists of the traditional multipliers (direct plus indirect over direct effects). These are more useful in an industry context where the relationship of the primary factors (labour, profits, etc.) are better defined and more meaningful than for commodities and final demand. One should note that large multipliers by themselves may be very misleading. For example, in the case of the Petroleum & coal products industry (Table II.C.2, line 25) ALBERTA shows a GDP multiplier of 13.68. This quotient is due to a very low corporate surplus coefficient at the refinery (direct effect) combined with a relatively high surplus coefficient at the extraction phase (indirect effect). It is clear that in integrated industries the valuation of the goods transferred (in this case crude petroleum) is to some extent arbitrary and can lead to enormous multipliers. A multiplier is only one simple measure which should be examined in conjunction with knowledge of capacity, sources of supply, and markets. This is particularly true for small industries where significant growth would lead to major structural changes and different supply patterns.

In the case of mineral fuels (II.C.3, line 5) both Ontario and Quebec show employment multipliers which are absurd. This result is due to the unreliability of the parameters for these industries which are so small as to be almost non-existent in these two provinces.

We have not included a table for production in this section since it would be identical II.B.4.

3. Table III : FINAL DEMAND SPACE

In these tables we have juxtaposed the effects of six standardized final demand vectors in terms of labour income, GDP, employment, and production. Table III.A gives a comprehensive view of the entire final demand spectrum and allows inter-provincial comparisons of the distributions. The final demand categories are as follows:

a) Transfers to persons - this is an exogenous household income which is first reduced by savings; taxes and then spread over the province specific personal expenditure pattern.

b) Machinery & Equipment - This sector is characterized by heavy import dependence and yields particularly low impacts.

c) Construction: Due to the large in-province labour component and relative high locally supplied materials, this sector has a high impact.

d) Government current expenditure is characterized by large direct labour and employment effects which yield a high in-province impact.

e) Foreign Exports - There is no direct leakage in this simulation since exports are assumed to be locally produced.

f) Rest of Canada Exports

Table III. B re-organizes the same data presented in III.A to permit standardized provincial comparisons. In these tables the total GDP impact is normalized to present province by province matrices. It is important to realize that this is a distribution of the Canadian effects only.

The bar graphs show the diagonal elements from tables II.B. Each bar is the proportion of the total Canadian impact that stays in the province of expenditure. Government expenditures has the highest local effect due to the large proportion of direct wages and salaries. Both of the export graphs reflect high in-province impacts since there is no immediate leakage of goods and services. This is because the import content of exports in typically very low. Construction investment has a generally lower local effect than exports yet the relatively large direct labour content keeps the proportions up. (Of course, it is assumed that the corporate surplus included in these G.D.P. measures remains in the province of production). Transfers to persons (or consumers expenditures) shows a somewhat lower local impact due to the greater diversity of goods in the standard consumer's bundle and especially the high proportion of consumer's durables coming from central Canada. Finally, investment in machinery and equipment reflects the high dependence on Ontario for this category of goods.

Appendix I. Mathematical Description of Tables

The regional industry-source inverse matrix* is composed of 11 x 11 submatrices as follows:

$$W = \begin{matrix} W_{1.1} & W_{1.2} & W_{1.11} \\ W_{2.1} & W_{2.2} & W_{2.11} \\ W_{11.1} & W_{11.2} & W_{11.11} \end{matrix}$$ inter-provincial inverse

A column of the inter-provincial inverse is the effect on each industry and province of a dollar of production in a given industry and province. In the tables presented in this paper, the inverse includes the induced effects of closing the model to the household sector.

The submatrices on the diagonal $W_{i,i}$ represent the in-province activity of each industry in a province. The column sum of matrix W_{ii} therefore is the total provincial production per dollar spent in each industry. The sum of all submatrices in a column j gives the total Canadian production per dollar spent in each industry of province j.

* For further elucidation see Chapter 7 of Structural Analysis Users Guide.

Now, given some primary factor Y (Y is expressed per dollar of production)

$$Y = (Y_1\ Y_2\ \ldots\ldots\ldots Y_{11})$$

we derive the direct and indirect factor per dollar spent in each province as

1) $F = YW$

For the purposes of this paper the factors used in calculating F are labour income, G D P, and employment.

It should be noted that if Y is simply a vector of 1's then F is the column total of W which is the production multiplier by industry by province (Table II B.4).

Some of the tables in this report (II.B) highlight the in-province effects. These are simply:

2) $F_i = Y_i\ W_{ii}$

Note that so far these measures are still expressed per dollar of production. The more common income and employment multipliers as shown in Tables II.C are calculated as follows:

3) $M_{ii} = Y_i\ W_{ii}\ Y_i^{-1}$

Where Y_i^{-1} is simply the diagonal matrix formed from the reciprocal of elements of Y_i.

In order to express these measures by commodity we require the market share matrices.

A column of the D matrix sums to 1 and distributes provincial commodity demand to producing sectors. The commodity space inverse giving Industry production by province per dollar of provincial commodity demand is WD.

Now, if we wish to examine the impact of an expenditure in a province we need a transformation from province of expenditure to province of production. Let us define the regional commodity share matrix as follows:

where $R_{i,j}$ is diagonal commodity by commodity matrix which represents the share of the total supply of commodities consumed in region j which were produced in region i.

In order to convert from province of production by industry to province of expenditure by commodity we transform the inverse as follows.

4) $Z = WDR$

Z is a 11 x11 block matrix, each component of which is an industry by commodity submatrix. The columns will be the commodity and province of purchased while the rows are the industry and province of impact. Now, in the same way as we summarized the provincial effects in equation 1 and 2 we can likewise transform equation 4 by

5) $C = YWDR$

This is the Canada total effect in terms of factor Y of an expenditure on each commodity and province. The in-province effects ar given by

6) $C_{ii} = Y_i \ (WDR)_{ii}$

These results are shown in Table I.B and a complete provincial distribution of effects of expenditures in each province are shown in tables I.C.1 through I.C.11

The last set of tables are final demand impacts for 6 standardized demand vectors (E) where E is a commodity space vector:

$$E = \begin{matrix} E_1 \\ E_2 \\ . \\ . \\ . \\ E_{11} \end{matrix}$$

provincial concatenation of commodity length vectors of a final demand category in each province

Tables III.A are calculated as the product CE for 6 vectors E. The tables compare the impact of these E vector on three primary factors and gross production.

I. INTRODUCTION

Dans ce document, nous essayons de réunir quelques-uns des résultats du modèle interprovincial d'entrées-sorties les plus en demande. Le document comprend une gamme de mesures, certaines par industrie et par province de production, d'autres par bien ou service et province d'achat. En plus des "multiplicateurs" habituels, il renferme six simulations de vastes agrégats de la demande finale qui montrent les effets des variations sur divers revenus par province. Un vecteur uniformisé des exportations de chaque province vers le reste du pays constitue un de ces agrégats.

Cette étude vise surtout à établir un cadre général à l'intérieur duquel il est possible de faire des comparaisons. Trop souvent on recourt aux multiplicateurs d'entrées-sorties sans faire mention du cadre dans lequel ils ont été calculés. Lorsqu'on utilise un modèle statique d'entrées-sorties dans le cadre d'une analyse partielle plutôt que dans une simulation de l'économie totale, on ne doit pas se servir du modèle dans l'absolu mais plutôt à des fins d'analyse comparative. Cette restriction est nécessaire étant donné la nature même du modèle, qui ne réagit pas aux limites de la capacité de production ni aux variations des répartitions moyennes que décrivent les paramètres du modèle. En outre, le modèle d'entrées-sorties ne constitue qu'une mesure imparfaite de l'incidence dans la mesure où il ne saisit pas les effets finals des revenus qu'absorbent les impôts, les bénéfices et les importations. Ces effets sont trop complexes pour être modélisés à l'aide d'un simple système linéaire et proportionnel, ce qui fait que la relation fonctionnelle entre les revenus et les dépenses perd de sa clarté. Par exemple, la taille du

multiplicateur du revenu obtenu à la suite de la fermeture aux ménages du modèle type d'entrées-sorties est très sensible à la propension marginale à consommer, qui est déterminée principalement par l'épargne et les impôts. Or, au cours de la dernière décennie, nous avons été témoins d'une augmentation graduelle du taux moyen d'imposition personnelle et, par conséquent, d'une diminution du multiplicateur du revenu que mesure le modèle fermé. Toutefois, les paiements de transferts sous la forme d'assurance-chômage, de régimes d'assurance-maladie, de pensions, etc., ont maintenu le pouvoir d'achat privé, mais ces paiements ne sont pas fonction directe des recettes des administrations publiques au titre de l'impôt sur le revenu généré par le système de production (comme le prouve l'accroissement de la dette). Pour cette raison, les multiplicateurs du modèle fermé deviennent moins significatifs ou moins aptes à saisir la totalité des effets de revenu. Certes, il existe des raisons de supposer un équilibre à long terme qui oblige en dernière analyse à relier les transferts aux personnes au revenu, bien que ces transferts puissent être financés à même les impôts sur les bénéfices des sociétés ou à l'aide d'autres sources de recettes publiques. Néanmoins, ces questions ne peuvent être étudiées qu'à l'intérieur d'un cadre exhaustif et sortent du champ d'application d'un simple modèle statique linéaire du système de production.

S'il n'est pas réaliste de compter sur un multiplicateur absolu, alors à quel type d'analyses ce genre de modèle peut-il servir? De toute évidence, l'approche la plus sûre consiste à effectuer des comparaisons. Cela ne veut pas dire que les comparaisons soient exemptes du biais mentionné ci-dessus, mais dans ce cas, il existe au moins une base commune cohérente. Ce document comprend une gamme de tableaux faisait ressortir

les différents aspects du système interprovincial, ce qui permet souvent de comparer un multiplicateur donné à d'autres mesures de référence, comme par exemple les six simulations types présentées au tableau III. On devrait acccorder une attention toute particulière aux répartitions provinciales des effets qui caractérisent ce genre de modèle. On peut examiner ces répartitions du point de vue des biens et services (tableaux I.C) et de la demande finale (tableaux III.A et III.B). Les personnes qui veulent en savoir plus long sur les multiplicateurs du revenu et de l'emploi trouveront un échantillon des multiplicateurs internes des provinces (par opposition à ceux du Canada entier) par secteur à 2 chiffres de la C.A.É. au tableau II.C.

Une dernière mise en garde s'impose. Ces mesures sont sujettes aux erreurs en raison de la faiblesse de la structure simple du modèle, de l'utilisation de conventions comptables arbitraires et, ce qui est tout aussi important, de la qualité des données qui, dans de nombreux secteurs, reposaient sur des hypothèses pures et simples. Telle est la situation actuelle des entrées-sorties interrégionales et, dans ce secteur, le Canada est certainement en bien meilleure position que la plupart des pays.

II. La base des données

Le modèle interprovincial de 1974 est fondé sur une grande quantité de données provinciales directement observées. Les renseignements sur les entrées et les sorties de la plupart des industries productrices de biens et sur les niveaux d'activité pour la plupart des services sont assez complets. On applique ces données aux structures nationales afin d'obtenir des estimations des services au niveau provincial. En règle générale, les données sur les dépenses finales par province sont disponibles, bien que seulement au niveau des agrégats. Bien entendu, il y a des problèmes conceptuels en ce qui concerne la province de dépense pour certains secteurs comme les biens d'équipement et le matériel de défense circulants. (Dans le même ordre d'idée, l'expression "province de production" est quelque peu arbitraire lorsqu'on parle de services comme les transports, les communications et les finances).

En vue d'estimer le commerce interprovincial, on a assemblé toutes les données existantes (principalement la destination des livraisons manufacturières et la statistique des transports de matières premières), puis on les a fait concorder avec les contraintes d'offre et d'utilisation tirées des tableaux provinciaux d'entrées-sorties. Comme les données du commerce étaient faibles à certains égards et comme les importations étrangères figuraient par province d'entrée plutôt que de destination, il importait d'avoir des contraintes d'offre et d'utilisation très strictes. D'ailleurs, cette nécessité devenait encore plus impérieuse au niveau provincial, puisque les données du commerce extérieur pour l'ensemble du pays sont relativement bonnes. En ajustant chaque industrie aux totaux témoins nationaux correspondants, on rendait les données cohérentes mais

pas nécessairement exactes puisque les différences étaient généralement réparties au prorata. Idéalement, le rapprochement des biens et services devrait améliorer le rapprochement entre les totaux de l'industrie et les contraintes pour le Canada, mais cette solution ne pourra être envisagée que lorsque le système statistique sera mieux intégré.

Le secteur du commerce interprovincial des services marchands est le plus faible de la base des données. Nous avons opéré une distinction quelque peu arbitraire entre services "locaux" et "nationaux". En ce qui concerne les services locaux, tels que la construction, le commerce de détail et les services personnels, nous supposons que la province fournit tous les services qui y sont demandés. Quant aux services nationaux, tels que les transports, les communications et les finances, nous supposons qu'ils suivent une structure générale du commerce qui correspond à la structure par agrégat des biens manufacturés, à l'exclusion des importations. La matrice du commerce qui en résulte fait ressortir la prédominance de l'Ontario en tant que fournisseur national, suivi dans une moindre mesure du Québec et, par la même occasion, elle tient compte d'un plus grand nombre de mouvements infrarégionaux dans la province.

On a besoin d'autres renseignements pour estimer l'emploi et pour fermer le compte des ménages. Il a fallu estimer les données de l'emploi à l'aide de valeurs d'imputation nationales puisque ces données n'existaient pas par province au niveau de détail exigé par la classification des entrées-sorties.

Pour fermer le modèle aux ménages, il faut des données sur l'épargne et les impôts personnels par province. Ces renseignements figurent dans la publication des comptes provinciaux (tableau 10, 13-213). Toutefois, l'utilisation de ces renseignements soulève quelques problèmes car les données sur les taux d'épargne provinciaux sont encore moins complètes que celles sur les taux nationaux. Comme l'épargne est un résidu, elle est touchée par les erreurs aux autres postes. Le taux d'épargne personnel de la Saskatchewan dépassait 20 % en 1974, ce qui se traduisait par des effets de revenu assez bas dans cette province (voir tableau III A.8). Néanmoins, il y a de bonnes raisons de croire que le taux d'épargne de la Saskatchewan est généralement plus élevé que celui des autres provinces.

III. Description des tableaux

Les tableaux sont répartis en trois sections. Le tableau I est présenté du point de vue de l'achat d'un dollar de chaque bien ou service par province; le tableau II, du point de vue de la valeur d'un dollar de production dans chaque industrie, et les tableaux III, du point de vue de la demande finale uniformisée par grand secteur. Toutes les simulations tiennent compte de l'effet de revenu attribuable à la fermeture du modèle aux ménages.

Tous les résultats sont exprimés en termes de:

a) REVENU DE TRAVAIL - somme de la rémunération des salariés et des bénéfices des entreprises individuelles;

b) PIB - revenu du travail plus excédent d'exploitation des sociétés;

c) EMPLOI - en années-personnes par $10,000 de production basée sur les proportions en 1974;

d) PRODUCTION BRUTE - Livraisons ajustées en fonction des variations de stocks.

I. Tableaux I ESPACE BIEN ET SERVICE

Ces tableaux présentent les effets des dépenses sur les biens et services. Le tableau I.A décrit la situation de l'offre dans chaque province en montrant les proportions de chaque bien ou service qui satisfont au total des besoins provinciaux en provenance de la province même, du reste du Canada et du reste du monde. De toute évidence, l'incidence locale d'une dépense dépend en grande partie des ratios d'autosuffisance de la province.

Le tableau 1.B représente les effets directs et indirects de l'achat d'un dollar de chaque bien ou service. Les résultats mesurent les répercussions internes dans les provinces en termes de revenu du travail, de PIB, d'emploi et de la production brute. Il importe de noter que les achats constituent l'élément clé de ces tableaux. En effet, si une province exporte entièrement sa production (par ex., le minerai de Terre-Neuve), alors il n'y a aucun achat local et l'effet sera nul. Dans ce cas, on doit se reporter au tableau II.B à l'industrie appropriée. De plus, la colonne "Canada" consiste en une moyenne de toutes les provinces pondérée par le total des achats de chaque bien ou service dans la province. Jusqu'à un certain point elle ne représente pas le total des effets au Canada puisqu'elle exclut les activités situées en dehors des provinces. Ces tableaux (1.B) ne sont pas des multiplicateurs par dollar de revenu direct mais plutôt par dollar d'achat, ce qui explique pourquoi le revenu du travail et le PIB sont, dans la plupart des cas, inférieurs à l'unité. Il ne faut pas oublier qu'un dollar de dépense doit résulter en un dollar de PIB (aux prix du marché) moins les importations directes et indirectes.

Toutefois, lorsque le modèle est fermé aux ménages, les dépenses se trouvent augmentées de façon implicite puisque le secteur de la consommation devient endogène. Par conséquent, le PIB total peut dépasser l'unité par dollar de dépense endogène malgré les fuites sous forme d'importations.

Pour des raisons de présentation, le tableau de l'emploi (I.B.3) est gradué de façon à présenter les années-personnes par $10,000 d'achat. Il faut se rendre compte que, dans certains cas, les mesures sont tirées d'un échantillon statistique très petit et très instable. Dans les petites provinces, la mesure de l'emploi peut être particulièrement inexacte à ce niveau de détail en raison du nombre de travailleurs à temps partiel ou d'autres travailleurs non salariés, qui tendent à dominer dans les établissements de petite taille.

Pour ces résultats, on se sert d'une relation entre la production et l'emploi fondée sur l'année 1974. L'emploi de données courantes réduirait la moyenne générale d'environ 33 % en raison de salaires moyens plus élevés.

Le tableau I.C montre, pour chaque province, la répartition du PIB entre toutes les provinces. Ce tableau est assez représentatif des facteurs retenus dans ce document. Pour cette raison et pour économiser l'espace, nous avons décidé de ne pas fournir de tableaux semblables pour le revenu du travail, l'emploi et la production.

On peut se servir des tableaux du PIB pour obtenir une approximation du modèle interrégional. La plupart des analyses de projet consistent à coder les dépenses de projet selon le groupe de bien ou service et la province d'achat appropriés. Le modèle calcule ensuite les effets directs et indirects par province et industrie. Lorsque le codage au niveau des 96 biens et services est terminé, il ne reste qu'à appliquer les principaux postes aux lignes appropriées du tableau I.C. Comme les relations sont linéaires, on peut additionner les effets totaux résultants pour obtenir l'incidence totale par province en termes du PIB. (On peut calculer ces effets en termes d'emploi en utilisant les ratios des tableaux I.B.3 et I.B.2). Cette méthode peut certes devenir assez fastidieuse lorsqu'un grand nombre de biens et services entrent en jeu mais, pour la plupart des analyses de projet, le nombre de biens et services importants est très restreint.

2. Tableau II ESPACE INDUSTRIE

Le tableau II présente les mesures et les multiplicateurs de l'incidence totale par province de production au niveau moyen de l'industrie, ce qui correspond à peu près au niveau des activités à deux chiffres de la C.A.É. Afin de donner un aperçu de la taille de chaque secteur par province sans révéler aucun renseignement confidentiel, le tableau II.A présente l'ordre de grandeur relative de la production de chaque industrie. Pour bien utiliser ces mesures, il importe de conserver une idée de leur grandeur puisqu'elles ne sont pas valides au-delà d'une certaine étendue par rapport à leurs niveaux réels de 1974. De fait, dans les cellules où les niveaux de production sont particulièrement bas, les mesures des revenus totaux peuvent être très grandes à cause d'excédents d'exploitation négatifs ou d'autres anomalies. Dans certains cas, une industrie n'est représentée dans une province que par un bureau de vente, ce qui, à proprement parler, correspond à un mauvais codage puisqu'elle aurait dû être classée comme activité de commerce de gros.

Le tableau II.B, présenté du point de vue de l'industrie et de la province de production plutôt que de celui du bien ou service de la province d'achat, est analogue à celui de la section I.B. Les observations concernant le tableau I.B. demeurent pertinentes dans le cas du tableau II.B.

Le tableau II.C est composé des multiplicateurs classiques (effets directs et indirects sur effets directs). Ces multiplicateurs sont plus utiles dans un cadre industriel car les relations entre les facteurs primaires (travail, bénéfices, etc.) y sont mieux définies et plus significatives que pour les biens et services et la demande finale. Il est bon de noter que de gros multiplicateurs utilisés seuls peuvent être très trompeurs. Par exemple, dans le cas de l'industrie des produits du pétrole et du charbon (tableau II.C.2, ligne 25), l'ALBERTA possède un multiplicateur du PIB d'une valeur de 13.68. Ce quotient est attribuable à un très petit coefficient d'excédent d'exploitation des sociétés à la raffinerie (effet direct), auquel s'ajoute un coefficient d'excédent relativement élevé à l'étape de l'extraction (effet indirect). Il paraît évident que, dans les industries intégrées, l'évaluation des biens et services transportés (dans ce cas-ci le pétrole brut) est dans une certaine mesure arbitraire et peut résulter en d'énormes multiplicateurs. Un multiplicateur n'est qu'une mesure simple qui devrait être examinée conjointement avec les renseignements sur la capacité, les sources d'approvisionnements et les marchés. Cela est particulièrement vrai en ce qui concerne les petites industries où une croissance importante entraînerait des changements structurels d'envergure et des structures d'offre différentes.

Dans le cas de combustibles minéraux (II.C.3, ligne 5), l'Ontario et le Québec possèdent tous deux des multiplicateurs de l'emploi absurdes. Ce résultat est imputable au manque de fiabilité des paramètres de ces industries, qui sont quasi-inexistantes dans ces deux provinces.

Nous n'avons pas cru bon de joindre à cette section un tableau de la production étant donné qu'il serait identique au tableau II.B.4.

3. Tableau III: ESPACE DEMANDE FINALE

Dans ces tableaux, nous avons juxtaposé les effets des six vecteurs uniformisés de la demande finale en termes de revenu de travail, de PIB, d'emploi et de production. Le tableau III.A donne une vue complète de toute la gamme de catégories de la demande finale et permet des comparaisons interprovinciales des répartitions. Les catégories de la demande finale sont les suivantes:

a) Transferts aux personnes - il s'agit là d'un revenu exogène des ménages dont on commence par enlever l'épargne et les impôts et que l'on répartit ensuite selon la structure particulière des dépenses personnelles de chaque province.
b) Machines et matériel - Ce secteur est caractérisé par une forte dépendance sur les importations et se traduit par une incidence particulièrement faible.
c) Construction: En raison de l'importance de la composante interne de travail des provinces et du niveau relativement élevé de matériaux achetés sur place, ce secteur a une forte incidence.
d) Les dépenses publiques courantes se caractérisent par des effets directs importants en termes de travail et d'emploi, ce qui se traduit par une incidence provinciale interne élevée.
e) Exportations étrangères - Il n'y a aucune fuite directe dans cette simulation étant donné qu'on suppose que les exportations sont produites sur le marché local.
f) Exportations du reste du Canada.

Le tableau III.B réorganise les données déjà présentées au tableau III.A de façon à permettre des comparaisons provinciales uniformes. On a uniformisé l'incidence totale du PIB de ces tableaux pour présenter les matrices province par province. Il importe de se rendre compte qu'il s'agit uniquement d'une répartition des effets canadiens.

Les graphiques à tuyaux d'orgue montrent les éléments diagonaux des tableaux II.B. Chaque tuyau d'orgue représente la proportion de l'incidence canadienne totale qui reste dans la province de dépense. Les dépenses publiques entraînent les effets locaux les plus importants en raison de la proportion élevée des salaires et traitements directs. Les deux graphiques des exportations font ressortir une incidence interne élevée dans les provinces étant donné qu'il n'y a aucune fuite immédiate de biens et services. Cela tient au fait que les exportations contiennent habituellement très peu d'importations. En règle générale, les investissements dans la construction ont des effets locaux plus faibles que les exportations mais leur contenu direct relativement important en main-d'oeuvre contribue à maintenir les proportions élevées (bien entendu, on pose l'hypothèse que l'excédent d'exploitation des sociétés compris dans ces mesures du PIB demeure dans la province de production). Les effets locaux des transferts aux personnes (ou dépenses de consommation) sont un peu plus faibles du fait de la grande diversité des biens et services que l'on trouve dans le panier type du consommateur et surtout à cause de la forte proportion de biens durables de consommation qui proviennent du centre du Canada. Finalement, les provinces dépendent fortement de l'Ontario en ce qui concerne les machines et le matériel.

PROPORTION DE L'IMPACT GENEREE DANS LA PROVINCE

Appendice 1. Description mathématique des tableaux

La matrice* régionale inverse de l'espace industrie se compose des sous-matrices 11 x 11 suivantes:

$$W = \begin{pmatrix} W_{1.1} & W_{1.2} \cdots W_{1.11} \\ W_{2.1} & W_{2.2} \cdots W_{2.11} \\ \vdots & \vdots \quad \vdots \quad \vdots \\ W_{11.1} & W_{11.2} \cdots W_{11.11} \end{pmatrix}$$ Matrice inverse interprovinciale

Les colonnes de la matrice inverse interprovinciale représentent l'effet d'un dollar de production dans une industrie et une province donnée sur chaque industrie et chaque province. La matrice inverse que l'on trouve dans les tableaux du présent document comprend les effets produits par la fermeture du modèle au secteur des ménages.

Les sous-matrices de la diagonale $W_{i,i}$ représentent l'activité interne de chaque industrie dans la province. La somme des colonnes de la matrice W_{ij} correspond donc au total de la production provinciale par dollar dépensé dans chaque industrie. La somme de toutes les sous-matrices de la colonne j équivaut à la production canadienne totale par dollar dépensé par chaque industrie de la province j.

* Pour plus d'explications, voir le chapitre 7 du Guide d'utilisation de la Division de l'analyse structurelle.

Or, étant donné un facteur primaire Y (exprimé en dollars de production)

$$Y = (Y_1 \quad Y_2 \quad \ldots\ldots\ldots Y_{11})$$

nous calculons les facteurs direct et indirect par dollar dépensé dans chaque province à l'aide de l'identité suivante:

$$1) \quad F = YW$$

Il est à noter que, si Y est un simple vecteur composé de 1, alors F est égal au total de la colonne de W, qui correspond au multiplicateur de la production par industrie et par province (Tableau II.B.4)

Certains tableaux de la présente étude (II.B) font ressortir les effets provinciaux internes, qui sont:

$$2) \quad F_i = Y_i \quad W_{ii}$$

Jusqu'ici, toutes les mesures sont exprimées par dollar de production. On calcule de la façon suivante les multiplicateurs du revenu et de l'emploi utilisés couramment (tableau II.C):

$$3) \quad M_{ii} = Y_i \quad W_{ii} \, Y_i^{-1}$$

où Y_i^{-1} est tout simplement la matrice diagonale formée à l'aide de la réciproque des éléments de Y_i.

Pour exprimer ces mesures par bien et service, il nous faut les matrices des parts du marché.

$$D = \begin{pmatrix} D_1 & & & \\ & D_2 & & \\ & & \ddots & \\ & & & D_{11} \end{pmatrix}$$

D_i = Matrice des parts du marché pour la région i

Une colonne de la matrice D a une somme égale à l'unité et répartit la demande provinciale de biens et services selon les secteurs de production. WD constitue la matrice inverse de l'espace bien et service qui équivaut à la production de l'industrie par province par dollar de demande provinciale de biens et services.

Si nous désirons étudier l'incidence d'une dépense dans une province, nous devons convertir les valeurs de la province de dépense en province de production. Définissons la matrice régionale des parts de biens et services de la façon suivante:

$$R = \begin{pmatrix} R_{1,1} & R_{1,2} & \cdots & R_{1,11} \\ R_{2,1} & R_{2,2} & \cdots & R_{2,11} \\ \vdots & & & \vdots \\ R_{11,1} & R_{11,2} & \cdots & R_{11,11} \end{pmatrix}$$

Matrice provinciale des parts de biens et services

où $K_{i,j}$ est la matrice diagonale bien et service par bien et service, qui correspond à la part de l'offre totale de biens et services consommée dans la région j mais produite dans la région i.

Pour convertir la matrice de province de production par industrie en province de dépense par bien ou service, il faut effectuer la transformation suivante de la matrice inverse:

4) $Z = WDR$

Z est une matrice composée de 11 x 11 cellules, dont chaque composante est une sous-matrice industrie par bien ou service. Aux colonnes figurent le bien ou service et la province d'achat et aux lignes, l'industrie et la province d'incidence. Nous pouvons transformer l'équation 4 de la même façon que pour les équations 1 et 2, dont nous avions additionné les effets provinciaux:

5) $C = YWDR$

ce qui constitue l'effet total canadien en termes du facteur Y d'une dépense en chaque bien ou service et dans chaque province. Les effets provinciaux internes sont obtenus de la façon suivante:

6) $C_{11} = Y_1 \ (WDR)_{11}$

Ces résultats paraissent au tableau I.B et la répartition provinciale complète des effets des dépenses dans chaque province figure aux tableaux I.C.1 à I.C.11.

Le dernier ensemble de tableaux représente l'incidence de la demande finale exprimée à l'aide de six vecteurs uniformisés de demande (E), où E est un vecteur de l'espace bien et service:

$$E = \begin{pmatrix} E_1 \\ E_2 \\ . \\ . \\ E_{11} \end{pmatrix}$$

Concaténation provinciale des vecteurs bien et service d'une catégorie de demande finale dans chaque province

On calcule les tableaux III.A en effectuant le produit CE pour 6 vecteurs E. Les tableaux comparent l'incidence de ces vecteurs E sur trois facteurs primaires et la production brute.
